- Virtualization
    - Virtualization renders a moving window of items instead of the full dataset. It preserves the total scrollable space, calculates the visible range from the scroll position, and renders that range with some overscan. This reduces mounted components and DOM work. I'd combine it with pagination when data volume is large, and account for dynamic heights, persistent editing state, accessibility, and scroll stability.
- Component Re-render because
    - State changed
    - Parent re-rendered
    - Context it consumes changed
- Re-render vs Remount
    - When a react component re-render it does not necessarily means that the DOM is updated as well.
- Debouncing: wait for a pause
- Throttling: limit execution frequency during continuous activity
- HOF
    - t's a function that **accepts another function as an argument, returns a function, or does both**.
- Callback
    - A function passed to another function
- Currying
    - : turn multiple arguments into successive function calls
- Higher-Order Component
    - A HOC accepts a component and returns an enhanced component:
- JavaScript has global/module scope, function scope, and block scope.
- Var does not respect block scope
- `??` uses it only for `null` or `undefined`.
-
